## 1.0 EXECUTIVE SUMMARY

Supported by a sixth year of funding from the Belgrade Lakes Association (BLA), and a second year of collaboration with Colby College (CC), Loon Conservation Associates (LCA) and the BLA continued a study of common loons (*Gavia Immer*) on Great Pond and Long Pond. Loons are a key indicator of aquatic integrity for lakes, and this initiative provides an opportunity to confirm the current population status, identify major threats, and create long-term, sustainable conservation solutions designed to aid the current population.

Engaging and educating local volunteers and CC student interns to conduct surveys with professional guidance is a key component of the project. Formal training was conducted in May by LCA. Results published in this report are taken from data gathered by LCA, BLA and CC.

In 2024, Great Pond and Long Pond were surveyed bi-weekly by LCA, and alternatively by BLA volunteers, and CC student interns and staff. Based on well-defined criteria for an established loon territory, a total of 23 territorial pairs were documented and 18 of these pairs nested. From seven successful nests nine chicks hatched and six survived to > six weeks of age – an age defined as fledging for modeling purposes. Overall productivity on Great Pond and Long Pond in 2024 was 0.26 fledged young per territorial pair.

Historically, nesting loons have benefited from the use of artificial nesting islands (rafts). Pairs nesting on rafts have had better success than pairs nesting naturally. In 2024, the same number of rafts were deployed as 2023; three rafts on Long Pond (Beaver Cove, Lynch Cove and Tracy Cove), and three on Great Pond (Finger Reef, Horse Point and Robbins Mill). The raft previously placed in Austin Bog was moved to Finger Reef. Three of the six rafts were used for nesting (50%), and two of the three nests were successful (67%). Comparatively, there were a total of 15 natural nest attempts on the two lakes, and six nests were successful (40%).

Banding (color-marking) loons is a key conservation measure for comprehensive population studies. Marked individuals can be tracked to gain further information on territory boundaries, between-year territory fidelity, mate switching, estimated minimum and long-

term survivorship, intra-seasonal movements, and recruitment. In 2024, the capture and banding program was continued. A total of three adult loons were captured and banded on Great Pond. One chick was also captured and sampled for laboratory analysis, but it was too young to band.

Significant findings/outcomes:

- Monitoring of a larger banded population allowed confirmation of individual survival, and mate and territory fidelity with high certainty. Findings from the 2024 field monitoring season looking at adult loons banded since 2020 included:
  - Thirty of 36 adult loons returned (83%).
  - Eighteen of the 30 returning loons occupied the same territory (60%).
  - Five of 14 banded pairs remained together (36%). This is down from 50% in 2023, largely due to weak territory fidelity of 2023 banded pairs.
  - Seven pairs from different territories were banded in 2023 (14 adults). Only two of the seven pairs remained together in 2024, although all 14 banded adults returned. Only one chick was produced from these seven territories in 2024.
  - An ABJ (adult banded as a juvenile) was confirmed in breeding plumage on several occasions on Long Pond. It was identified as the chick originally banded in the Long Pond, Castle Island territory in 2021. This is the first confirmed case of a loon returning to its natal lake since the project began in 2019.
- Three of the six rafts deployed were used (50%). Constant disturbance from other loons and displacement of 2023 residents in both Tracy Cove and Beaver Cove, Long Pond, is suspected as the most likely cause of neither of these pairs nesting on the rafts placed there.
- Although a chick was never observed in the Finger Reef, Great Pond territory, evidence of shell remains on the raft, and close observation of the adults at hatch time were strong indicators a chick was hatched and lost, immediately.

- One deceased, adult loon was recovered from Pinkham Cove, Great Pond. Results of an examination at Avian Haven determined that the cause of death was lead poisoning from ingesting lead sinkers.
- Nesting was confirmed for the first time in the Great Pond, Otter Island territory. The male resident was originally banded in Snake Point Cove in 2008. The nesting pair hatched and fledged one chick.
- Long Point, Crooked Island, and Oak Island territories on Great Pond, and the W Boat Ramp territory on Long Pond were determined to be unoccupied in 2024. All other known, historical territories were occupied by a pair of loons.

## **2.0 INTRODUCTION**

Loons were first banded in the Belgrade Lakes in 1997. The effort was funded as part of a Maine Department of Environmental Protection, Regional Monitoring and Assessment Program (ReMAP). Ongoing monitoring and banding efforts were continued, sporadically, over the following decades, but were limited by a lack of funding.

Data gathered from the prior banding effort and occasional surveys provides some insight into the population status. Personal monitoring efforts conducted over the last two decades confirmed Long Pond has upwards of  $10\pm$  territorial pairs of loons, with knowledge of at least six territories known on Great Pond. Casual evidence suggests the population is relatively stable, with annual fluctuations in productivity, typical of the species throughout their range. However, recent declines in chick numbers observed by local residents and seasonal camp owners has generated concern about the health of the population.

Great Pond and Long Pond are vulnerable to multiple anthropogenic stressors, coupled with the potential impacts of climate change. More information is needed on the individual performance (i.e., reproductive success) and specific movements of individuals to better understand the status of the population.

### **3.0 OBJECTIVES**

Collaborate with BLA and CC to:

1. Conduct bi-weekly, comprehensive productivity surveys to identify territorial pairs, nesting pairs, nest success/failure, number of chicks hatched, and number of chicks fledged;
2. Consult on deployment and placement of artificial nesting rafts, where appropriate, to increase nest success rates, and minimize nest loss due to flooding and predation;
3. Engage and instruct citizen volunteers and CC interns on the basics of conducting comprehensive loon breeding surveys, and
4. Continue an active capture and banding program to better understand the status of the current loon population, and
5. Share all data acquired at both regional and national conferences to aid our understanding of the species status and trends over a wide geographical area.

### **4.0 STUDY AREA**

This study is limited to the entirety of Great Pond and Long Pond (including Ingham Stream and Ingham Pond), Kennebec County, Maine (Figure 1).

Figure 1. The Belgrade Lakes Study Area. Courtesy of Google Earth.

## 5.0 METHODS

### 5.1 GROUND SURVEYS

All known or potential loon territories and surrounding areas were surveyed by LCA, BLA volunteers, and CC student interns and staff using binoculars and/or a spotting scope, when needed. Surveys were conducted by boat, or alternatively from shore. Comprehensive surveys began in May and ended in August, although BLA volunteers and CC staff continued to conduct chick survival surveys well into the fall. Confirmed territories occupied by loon pairs were prioritized and surveyed bi-weekly at a minimum. To minimize impacts on the loons, surveys were conducted from the greatest distance possible. If nesting evidence was obscured by vegetation, it necessitated searching for nest evidence by foot. All known nesting sites were checked regularly for nesting evidence.

Loon territories were delineated according to observed territorial behavior by a loon pair such as close physical association, and defensive posturing and calling along borders.

Territories are used by pairs for feeding, resting, breeding, nesting and chick rearing, and are protected against incursion by other loons (and sometimes waterfowl) for a minimum of four weeks. Territories are used as a unit of reference in describing loon breeding activity and are recognized as being either *established* or *transitional*. Established territories have consistent occupancy for at least three seasons; transitional territories exhibit inconsistent occupation.

Nesting pairs were defined as those laying at least one egg; a nesting attempt was evidenced by a constructed nest dish or scrape with at least one egg present or fresh eggshell fragments. Successful nesting pairs hatched at least one chick. Causes of nest failure were attributed according to evidence observed.

Chicks hatched were recorded as those that hatched completely out of their eggs, not necessarily departing from the nest. For this report, we define the terms *chick* and *fledgling* as follows: *chicks* refer to loon young  $\leq$  six weeks of age post-hatching and fledglings or “fledged young” refer to loon young  $>$  six weeks of age. Sub-adult loons in alternate plumage are recorded as immatures (ages 1-2). The number of loon chicks to survive past six weeks of age, were assumed to have fledged.

## 5.2 ARTIFICIAL NESTING ISLANDS

Rafts were floated in territories that met specific criteria for flotation; including knowledge of 1) a history of nest failures due to predation and/or flooding, 2) wind and wave action patterns relative to each territory, 3) loon territorial boundaries and proximity to neighboring territories, 4) previous traditional and non-traditional nest site locations, 5) boat traffic patterns relative to the specific territory, and 6) shoreline activities.

## 5.3 LOON CAPTURE AND SAMPLE COLLECTION

Loons were captured using well-established night lighting and playback techniques. Adult and juvenile birds were leg banded with USFWS aluminum bands and a unique combination of plastic-colored bands, enabling identification of individual birds to be made from a distance in future observations. Chicks were not banded if their legs were too small to hold adult-size bands. All sampling was accomplished using non-lethal methods.

## 5.4 DEFINING REPRODUCTIVE SUCCESS

Reproductive success was evaluated according to four parameters; 1) nesting frequency, 2) hatching success, 3) chick survivorship, and 4) overall productivity. Nesting frequency was defined as the number of nesting pairs per total territorial pairs. This measure indicates the percent of the total potential breeding population that attempts to reproduce each season. The rate of success by these pairs, or hatching success, was measured through the number of chicks hatched by these pairs. Chick survivorship was defined as the number of chicks surviving divided by the number of chicks hatched. Overall productivity is a combination of the prior three parameters and measured through fledged young per territorial pair (CS/TP).

## 6.0 RESULTS

### 6.1 OVERALL STUDY AREA PRODUCTIVITY

During the 2024 field season 23 territorial pairs were identified. Of the 23 pairs, 18 nested, and seven successful nests hatched nine chicks; six survived to fledge. This yielded a nesting frequency of 0.78, a hatching success of 0.50, and chick survival of 0.66. Overall productivity was 0.26 fledged young per territorial pair (Table 1).

Table 1. Common Loon Population and Productivity, Great Pond and Long Pond, 2024.

<i>Population</i>		<i>Reproductive Success</i>	
Territorial Pairs	23	Nesting Frequency	0.78
Nesting Pairs	18	Hatching Success	0.50
Chicks Hatched	9	Chick Survivorship	0.66
Chicks Surviving	6	Overall Productivity	0.26

#### 6.1.1 GREAT POND PRODUCTIVITY

Thirteen territorial pairs were identified on Great Pond. Of the 13 pairs, 11 pairs nested, and six successful nests hatched eight chicks. Five chicks survived to fledge. This yielded a nesting frequency of 0.85, a hatching success of 0.73, and chick survival of 0.63. The overall productivity was 0.38 fledged young per territorial pair (Table 2, Figure 2).

Table 2. Common Loon Population and Productivity, Great Pond, 2024.

<i>Population</i>		<i>Reproductive Success</i>	
Territorial Pairs	13	Nesting Frequency	0.85
Nesting Pairs	11	Hatching Success	0.73
Chicks Hatched	8	Chick Survivorship	0.63
Chicks Surviving	5	Overall Productivity	0.38

Figure 2. Nesting Loons, Ram Island, Great Pond.

#### 6.1.2 LONG POND PRODUCTIVITY

Ten territorial pairs were identified on Long Pond. Of the 10 pairs, seven nested, and one successful nest hatched one chick, which survived to fledge. This yielded a nesting frequency of 0.70, a hatching success of 0.14, and chick survival of 1.00. Overall productivity was 0.10 fledged young per territorial pair (Table 3, Figure 3).

Table 3. Common Loon Population and Productivity, Long Pond, 2024.

<i>Population</i>		<i>Reproductive Success</i>	
Territorial Pairs	10	Nesting Frequency	0.70
Nesting Pairs	7	Hatching Success	0.14
Chicks Hatched	1	Chick Survivorship	1.00
Chicks Surviving	1	Overall Productivity	0.10

Figure 3. Adult and chick, 2024.

## 6.2 PRODUCTIVITY AND NEST FAILURE RESULTS BY LAKE/TERRITORY, 2024.

Productivity results were analyzed and documented by lake/territory, including nest failures. A total of 11 nest failures were recorded. There were six cases of abandonment, one confirmed case of mammalian predation, one confirmed case of human disturbance, and three cases of nest failure for unknown reasons (nest found empty with no evidence). A total of nine abandoned eggs were collected (Table 4).

Table 4. Productivity and Nest Failure Results by Lake/Territory, 2024.

Lake/Territory	TP*	NP*	CH*	CS*	NF*	CAUSE OF NEST FAILURE
<b>GREAT POND:</b>						
Marina	Y	N	0	0	0

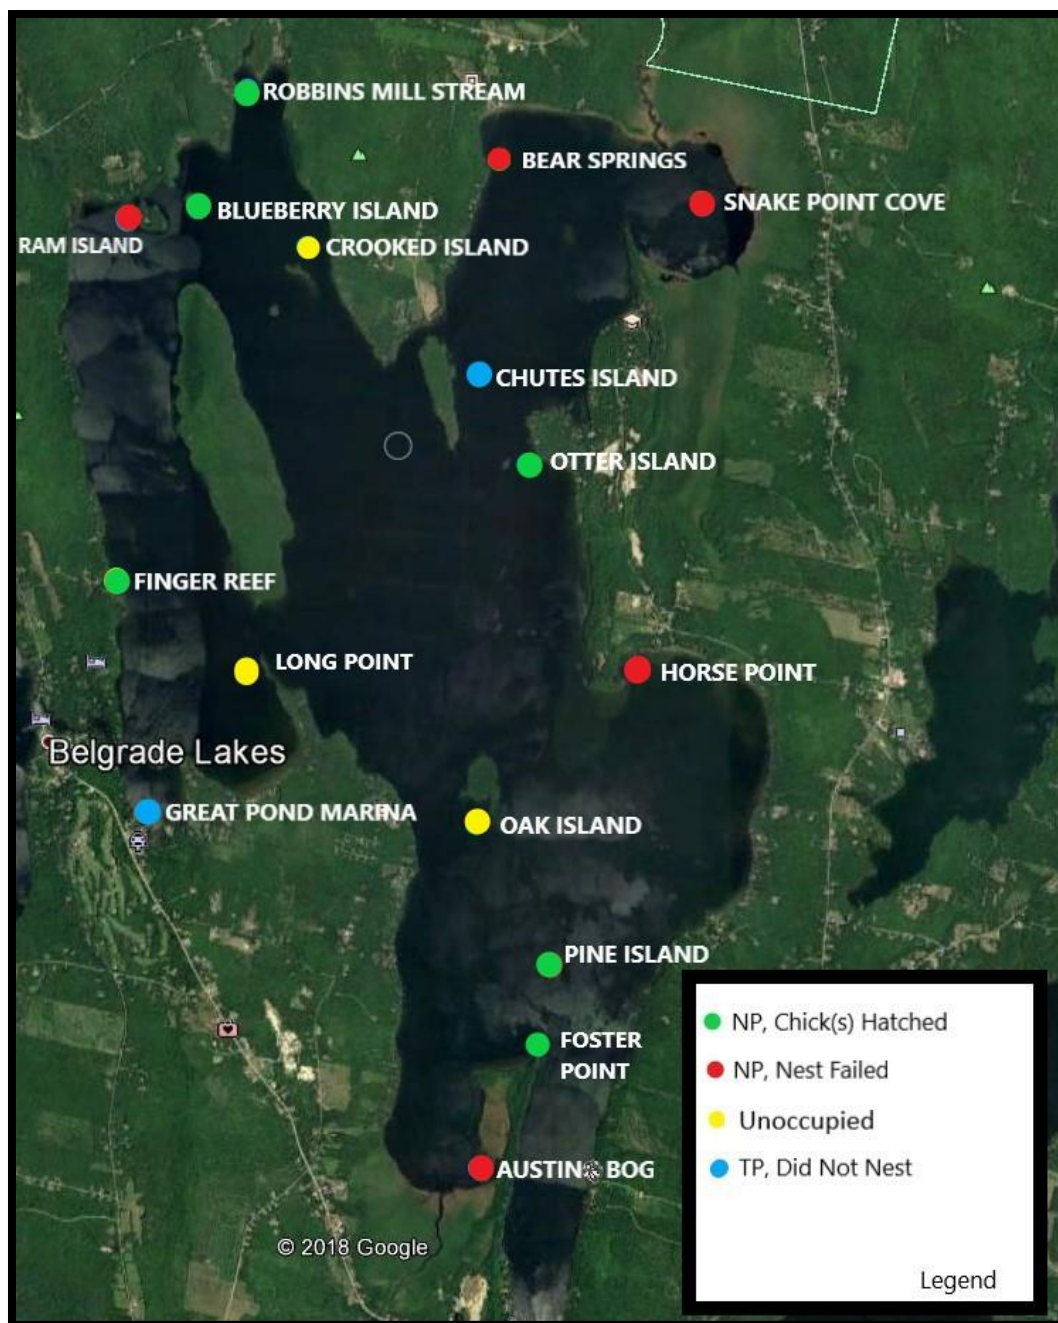

Figure 5. Common Loon Population and Productivity, Long Pond, 2024. Courtesy of Google Earth.

### 6.3 USE OF ARTIFICIAL NESTING ISLANDS (RAFTS)

Six artificial nests rafts were floated in 2024, and three were used (50%). Two of the three pairs nesting on rafts successfully hatched chicks (67%). In comparison, there were 15 natural nest attempts and six were successful (40%), (Table 5, Figure 6).

Table 5. Comparative Loon Nesting Summary: Raft vs. Natural Nests, Great Pond and Long Pond, 2024.

<b><i><u>Raft Nests</u></i></b>	<b><i>2024</i></b>	<b><i><u>Natural Nests</u></i></b>	<b><i>2024</i></b>

## 6.4 CAPTURE AND BANDING

In 2024, 2 adult loons were captured and banded, and one adult originally banded in 2008 was recaptured, and his silver band was replaced. Additionally, the chick from Otter Island was captured and blood samples were obtained for analysis. It was too young to band. (Table 6, Figure 7).

Table 6. Captured and Banded Loons, 2024.

Lake/Territory	Band #	Year	Sex	Age*	Left Leg Top	Left Leg Bottom	Right Leg Top	Right Leg Bottom
<b>Great Pond:</b>								
Robbins Mill	1238-28523	2024	M	ATY	Green Dot	White	Orange Stripe	Silver

Figure 7. Colby interns Barlow Herbst and Jodie Tsih holding loons during banding, 2024.

## 6.5 BANDED LOON RE-OBSERVATIONS AND RECOVERIES

Loons were first banded on Great Pond and Long Pond in 1997. Between 1997 and 2023, 57 loons were banded (49 adults and eight juveniles). In 2024, 32 banded adults were confirmed on Long Pond and Great Pond. All breeding loons were confirmed as either banded, with a positive confirmation or as unbanded (100% confirmation), (Table 7).

Table 7. Banded Loon Re-observations and Recoveries, 2024.

## 6.6 CONTAMINANT ANALYSIS

Lab analysis for contaminant levels in loons is not being conducted in 2024. Lab results for both mercury (Hg) and lead (Pb) contaminants have been analyzed since loons were first banded in 1997. The results over the past 25 years, including recent samples from as recent as 2020, show only low and moderate levels of these contaminants in both blood and feathers. These results do not indicate any levels of concern at this time.

## 6.7 MORTALITIES:

One deceased, adult loon was recovered from Pinkham Cove, Great Pond. Results of an examination at Avian Haven determined that the cause of death was lead poisoning from ingesting lead sinkers.

## 7.0 DISCUSSION

In 2024, 23 of 27 known territories (85%) were occupied by loon pairs. This continued high occupancy rate demonstrates a strong breeding base in numbers, with potential to sustain a healthy breeding population. Most of the high-quality nesting habitat is occupied on both lakes, but some suitable habitat remains where new territories could possibly emerge in the future.

Nesting conditions were relatively favorable in 2024. Water levels were managed well during extended rainy periods, and no nests were lost due to flooding, which is often a cause of loon nest failures.

Six of 11 nesting pairs on Great Pond were successful (73%), and one of seven pairs on Long Pond were successful (14%). Five of eight chicks on Great Pond fledged (63%), and the one chick hatched on Long Pond fledged (100%). Eleven nest failures of 18 nest attempts (61%), coupled with low mate fidelity were the primary factors in low overall productivity in the study area.

Identifying the cause of nest failures with some certainty is important in understanding population trends over time, as researchers weigh all the factors contributing to low productivity. In 2024 there were six cases where the cause of failure was egg abandonment.

Whole, intact eggs were left in the nest. These eggs were collected whenever possible, and they will be examined to determine if they were fertile, and if so, what was the stage of development.

The 2024 overall productivity of 0.26 CS/TP remains very low when compared to the established sustainable population threshold of 0.48 CS/TP. Looking at 2019 (0.35), 2020 (0.17), 2021 (0.35), 2022 (0.30), 2023 (0.26) productivity, no single year approaches 0.48 CS/TP. These consistently low productivity numbers over a six-year period are concerning. Further study and evaluation of population trends is warranted to help better understand the low productivity, and determine if there are additional conservation measures which could be implemented to enhance productivity.

Determining the occupancy status of territories, and accurately identifying all territories on both lakes is of critical importance when calculating productivity. This is extremely challenging on large lakes, especially Great Pond. Errors that might incorrectly add or subtract one or two territories, or err in determining occupancy status can dramatically alter the findings of this study. There was a high level of certainty of occupancy status in 2024, although some error is possible.

Similarly, confirming chick survival to six weeks of age is of critical importance. In 2024 consistent, comprehensive survey coverage resulted in 100% certainty of chick survival to six weeks of age.

When used by nesting pairs, artificial nest rafts have been highly effective when looked at over the six-year period of the study. Overall contributions to increased productivity are currently limited by a small percentage of known territories having rafts, and current usage rates.

Human disturbance of both nesting loons and loons on the lakes has been observed and documented. In 2024, there was one documented case of a nest failure due to human disturbance (Long Pond, Castle Island). Maps contained in this report help to inform the public about occupied loon territories, without divulging nest locations. With more knowledge and education, it is hoped the public will avoid disturbing nesting loons and exercise caution when boating and recreating in these areas of the lakes.

When used appropriately, signs can be used as a valuable education and conservation tool. Well-thought out and strategic usage of signage can help to reduce disturbance issues. Signs have been utilized broadly, often as part of well-developed conservation programs throughout common loon breeding ranges. Deploying more signs could reduce human disturbance issues.

Tracking movements, territory and mate fidelity, and long-term survival of banded loons is key to understanding the dynamics of the local population. For populations to thrive, long-term survival and mate fidelity are critical factors. Early findings raise concerns about loon fidelity in the study area. While return/survival rates are strong, mate fidelity is low. Only two of seven pairs banded in 2023 remained together in 2024 (29%) despite all the adults returning. Overall, only five of 14 pairs since 2020 have remained together (36%). Four years of data collection is a beginning. It's important to continue the in-depth monitoring, as well as continued banding of new individuals in future years.

In the first six years, this project demonstrated the effectiveness of collaboration between trained professional researchers and volunteer citizen scientists. Progress recruiting new citizen volunteers in the community has been slow, however. The new collaboration with CC offers the possibility of always having dedicated seasonal staff through the paid internships, which could assure the long-term sustainability of the project. This unique partnership allows for the development of sustainable conservation efforts, which in turn provides valuable information to local communities and scientists concerned about the health of loon populations.

## **8.0 RECOMMENDATIONS**

Common loons have responded well to dedicated human conservation measures designed to either stabilize a population or help a population rebound. However, these actions were implemented after years of research needed to accurately verify the status of the population, and identify past and present stressors, which may have led to population declines.

LCA recommends the following actions for 2025:

- With professional guidance, continue to use standardized survey methods to collect data on the number of territorial pairs, nesting pairs, location of nests, chicks hatched, and those surviving >six weeks of age.
- Review current utilization of nest rafts for possible changes to enhance the usage. Continue the strategic use of artificial nest rafts to aid productivity. When circumstances are appropriate, look to introduce new rafts into territories where nesting pairs are struggling to nest successfully.
- Procure and utilize nest monitoring cameras (trail cameras), as circumstances allow to better understand the causes of nest disturbance and failure.
- Continue the new collaboration with CC using student interns to conduct dedicated surveys, with an emphasis on training and oversight designed to support the students as self-guided, independent researchers.
- Connect with other loon conservation groups who are monitoring a significant banded population to compare fidelity findings and population status implications.
- Repeat capture and banding of loons through traditional night capture of adults with chicks, allowing individual identification and tracking of movements and survival over time.
- Continue to engage and inform the local community about loons on Great Pond and Long Pond through all available media.
- Increase outreach and education efforts to communicate and reduce threats from human nest disturbance, fishing line entanglement, boat wakes, etc. Specific steps could include signage at any nests where disturbance has been documented with any frequency, general education signage at boat launches, and installment of containers for disposing of fishing line.

## **9.0 ACKNOWLEDGMENTS**

LCA wishes to acknowledge the Belgrade Lakes Association and its' members, especially Dick Greenan, and the volunteers who participated in field surveys, Colby College and professor Cathy Bevier, and student interns Jodie Tsih and Barlow Herbst.
